Body shaving when electrodes are attached to record electromyograms or stimulate nerves

=====

“ ...

Preparation for the test measurement

Attaching the electrodes

An examiner will locate and mark the skin areas where electrodes will be attached. The discharge or stimulation electrodes are attached to these areas. See the attached diagram for the areas required for this study. Hair is first shaved from areas of approx. 5 cm × 5 cm using a disposable razor. The shaved areas are then cleaned by wiping them several times with cotton soaked in alcohol. Small self-adhesive electrodes are then applied to the prepared skin. The electrode cables are secured with skin-friendly adhesive tape to prevent them from slipping.

Comment: If you would like to know in advance who will perform the shaving and cleaning, please contact the study management before the study begins. It is also possible to shave and clean the electrode areas independently under supervision. Please also contact the study management before the study begins.
